Abstract

The last decades of developments in animal breeding, genetics, genomics and data recording technologies have allowed the evaluation of larger numbers of animal and animal traits than ever before. This should help make animal breeding choices more informed, but it also makes them far more complex. This complexity may be overwhelming farmers, thus compromising realization of potential genetic gain in live-stock industries. However, the effect of complexity of animal breeding choices on farmers' selection of animals has received very little theoretical consideration to date. This paper reviews the theoretical principles of complex decisions, contextualizes the findings to the field of animal breeding, and analyses how farmers and the animal breeding industry are currently dealing with complexity. According to the findings of the analyses of complex decisions in other fields, the complexity of animal breeding choices is likely to lead to farmers using conscious or unconscious simplifying strategies (heuristics) to handle such complexity. When these heuristics are ineffective, poor selection decisions and a potential loss of genetic progress can be expected. Further, studies using survey experiments to understand farmer behaviour and selection preferences may be compromised by the complexity of the survey's

Prediction of expected genetic variation within groups of offspring for innovative mating schemes

Dierck Segelke^{1,2*}, Friedrich Reinhardt¹, Zengting Liu¹ and Georg Thaller²

Abstract

Background: Experience from progeny-testing indicates that the mating of popular bull sires that have high estimated breeding values with excellent dams does not guarantee the production of offspring with superior breeding values. This is explained partly by differences in the standard deviation of gamete breeding values (SDGBV) between animals at the haplotype level. The SDGBV depends on the variance of the true effects of single nucleotide polymorphisms (SNPs) and the degree of heterozygosity. Haplotypes of 58 035 Holstein animals were used to predict and investigate expected SDGBV for fat yield, protein yield, somatic cell score and the direct genetic effect for stillbirth.

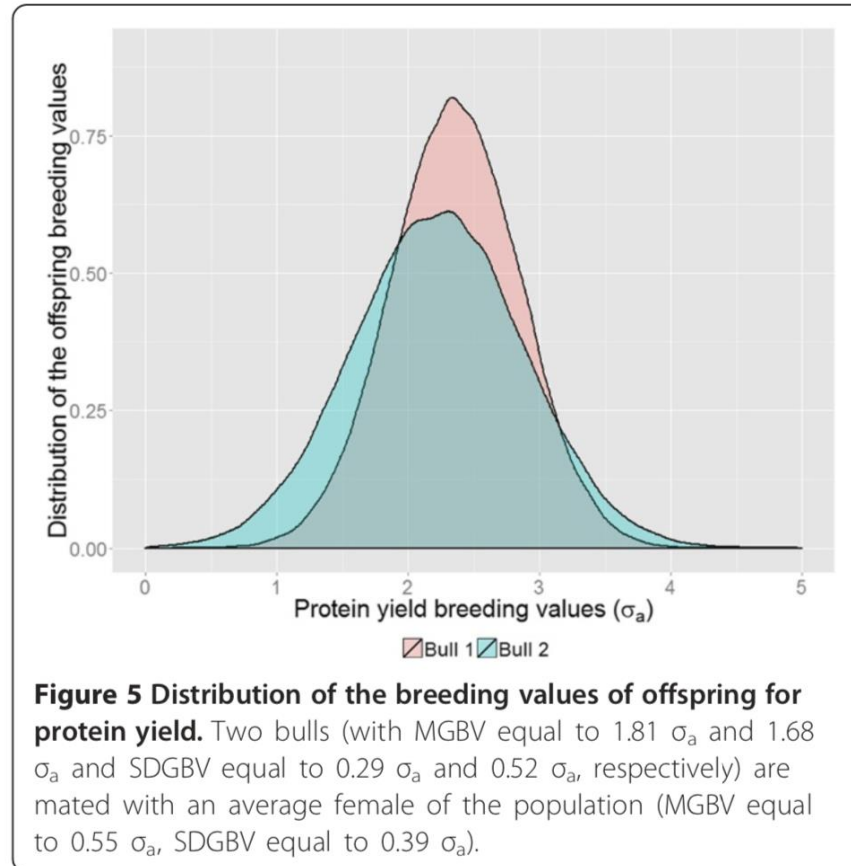

Results: Differences in SDGBV between animals were detected, which means that the groups of offspring of parents with low SDGBV will be more homogeneous than those of parents with high SDGBV, although the expected mean breeding values of the progeny will be the same. SDGBV was negatively correlated with genomic and pedigree inbreeding coefficients and a small loss of SDGBV over time was observed. Sires that had relatively low mean gamete breeding values but high SDGBV had a higher probability of producing extremely positive offspring than sires that had a high mean gamete breeding value and low SDGBV.

Conclusions: An animal's SDGBV can be estimated based on genomic information and used to design specific genomic mating plans. Estimated SDGBV are an additional tool for mating programs, which allows breeders to identify and match mating partners using specific haplotype information.

Table 3 Correlations (r) between SDGBV with real progeny variations for different traits per minimum number of offspring per sire

Minimum number of offspring per sire	Number of sires	r _{FY}	r _{PY}	r _{SCS}	r _{SBd}
10	409	0.65	0.56	0.60	0.50
50	146	0.90	0.78	0.80	0.72
100	84	0.93	0.83	0.88	0.69
150	48	0.93	0.90	0.90	0.78
200	32	0.93	0.91	0.87	0.85
300	20	0.96	0.93	0.94	0.82
500	7	0.98	0.88	0.90	0.90

PY = protein yield; FY = fat yield; SCS = somatic cell score; SBd = the direct genetic effect for stillbirth.

Large-effect pleiotropic or closely linked QTL segregate within and across ten US cattle breeds

Mahdi Saatchi¹, Robert D Schnabel², Jeremy F Taylor² and Dorian J Garrick^{1,3*}

High Impact Genes (markers): USAMRC

Could functional variants be more effective?

Genetic correlations between birth weight and GPE-trained birth weight MBV						
Marker set	size	GPE h ²	Evaluated population			
			SFA	Red Angus	Simmental	
F250 shared with 50K	33,869	0.45	0.35	0.44	0.25	
Significant GPE effects	279	0.34	0.44	0.43	0.25	
LD reduced	12	0.30	0.49	0.47	0.28	
NCAPG	1	0.06	0.31	0.32	0.22	

- Small sets of functional variants can explain meaningful phenotypic variation within and across populations
 - depends on number and size of effects - difficult to identify variants causing small effects, especially for traits influenced by many variants with small effects

RightMate Benefits:

- **Precision Breeding using Genomics**
- **Avoid Wasted Mating to offer more Marketable Bulls and Heifers**
- **Reduce Variation and More Uniformity**
- **Genetic Improvement at a Higher Speed**
- **Managing Inbreeding, Genetic Diversity and Customized Breeding using MateSel**

2023 RightMate Statistics (So far):

- ✓ **>11,681** Cows RightMated from **>75** Herds
- ✓ **> 4,400** Bulls/Cows RightChoice evaluated from **>62** Herds

RightMate Added-Value for Beef Industry:

- ✓ >10,000 Cows RightMated
- ✓ >5,000 RightMate Calves
- ✓ >2,000 RightMate Bull Calves goes to Commercial Herds
- ✓ ~100 calves per commercial herd bull.
- ✓ >\$5 extra genetic improvement (\$API)
- ✓ > \$1,000,000/year RightMate added-value in commercial beef sector.
- ✓ Much more \$ added value for replacement heifers, Seed-stock and AI bulls!
